

# Continuous Integration at Google Scale

By John Micco

Developer Infrastructure

- >10,000 developers in 40+ offices
- 5000+ projects under active development
- 17k submissions per day (1 every 5 seconds)
- Single monolithic code tree with mixed language code
- Development on one branch - submissions at head
- All builds from source
- 20+ sustained code changes per minute with 60+ peaks
- 50% of code changes monthly
- 100+ million test cases run per day

1. Continuous Integration Goals
2. Continuous Integration at Google
3. Practical Matters

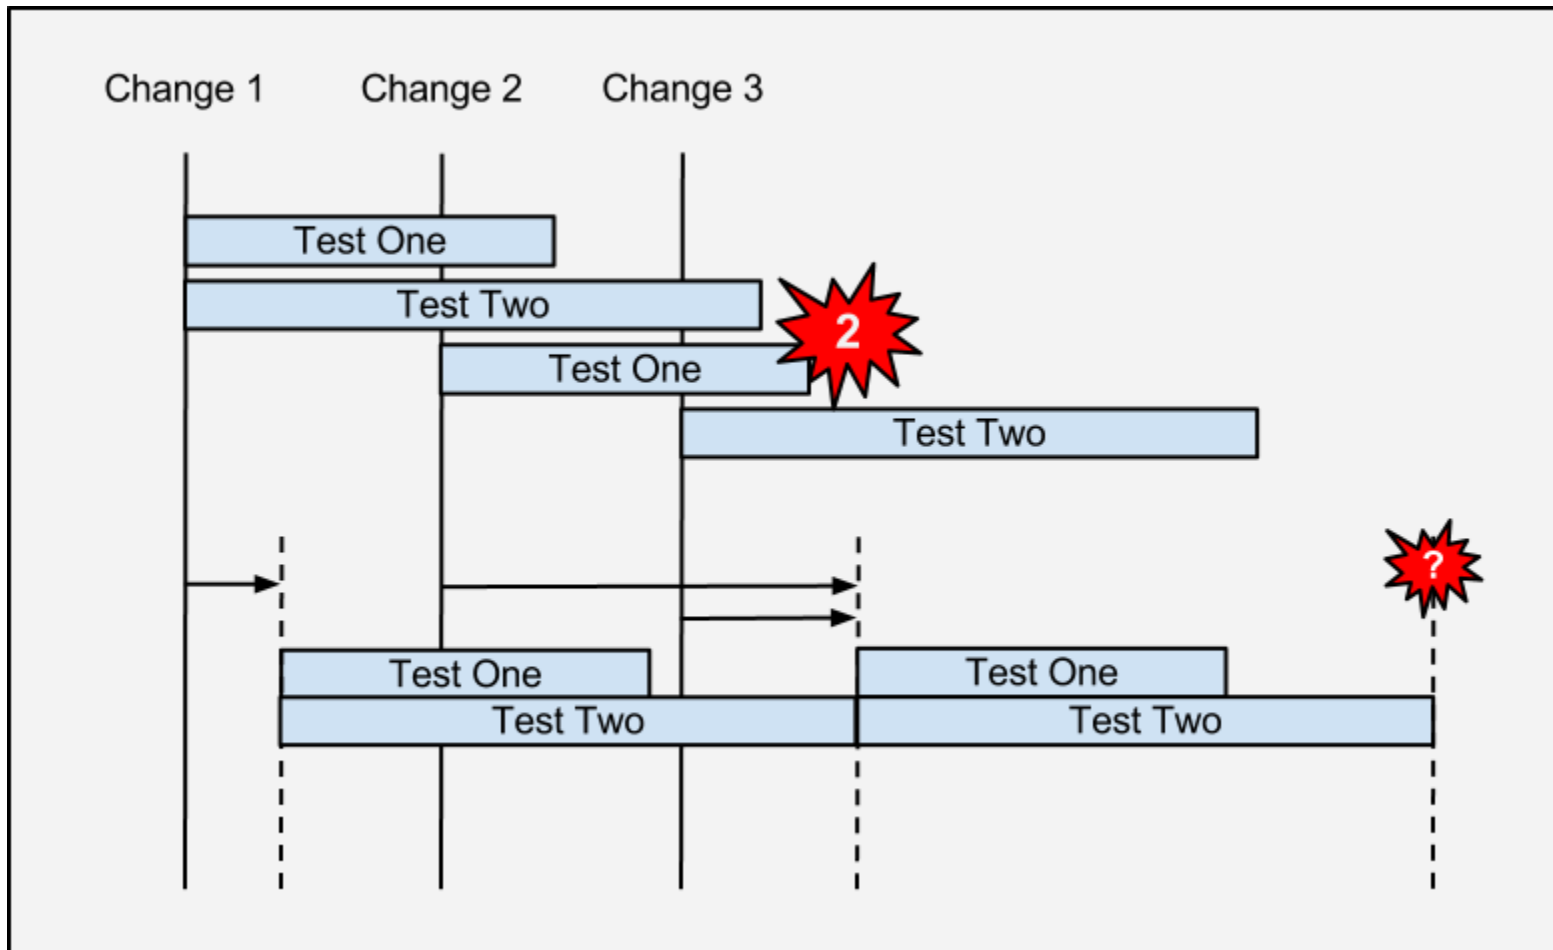

- Provide real-time information to build monitors
  - Identify failures fast
  - Identify culprit Changes
  - Handle flaky tests
- Provide frequent green builds for cutting releases
  - Identify recent green builds
  - Show results of all testing together
  - Allow release tooling to choose a green build
  - Handle flaky tests

- Develop Safely
  - Sync to last green changelist
  - Identify whether change will break the build before submit
  - Submit with confidence
  - Handle flaky tests

- Triggers builds in continuous cycle
- Cycle time = longest build + test cycle
- Tests many changes together
- Which change broke the build?

- Triggers tests on every change
- Uses fine-grained dependencies
- Change 2 broke test 1

Current Status **Grid** Test Log Coverage Project Maintenance Project Health (beta)

- Identifies failures sooner
- Identifies culprit change precisely
  - Avoids divide-and-conquer and tribal knowledge
- Lowers compute costs using fine grained dependencies
- Keeps the build green by reducing time to fix breaks
- Accepted enthusiastically by product teams
- Enables teams to ship with fast iteration times
  - Supports submit-to-production times of less than 36 hours for some projects

- Requires enormous investment in compute resources (it helps to be at Google) grows in proportion to:
  - Submission rate
  - Average build + test time
  - Variants (debug, opt, valgrind, etc.)
  - Increasing dependencies on core libraries
  - Branches
- Requires updating dependencies on each change
  - Takes time to update - delays start of testing

- Makes testing available before submit
- Uses fine-grained dependencies
  - Recalculate any dependency changes
- Uses same pool of compute resources at high priority
- Avoids breaking the build
- Captures contents of a change and tests in isolation
  - Tests against head
  - Identifies problems with missing files
- Integrates with
  - submission tool - submit iff testing is green
  - Code Review Tool - results are posted to the review thread

## Pending CL 30795386 : Presubmit Still Running

### ▼ Still Running (1)

//javatests/com/google/payments/testing/malbec/scenarios/fromconsole/sellersignup:LargeTapTests [\[Details & Test History\]](#)

### ▼ Newly Failing (1)

//javatests/com/google/moneta/storedvalue/service:LargeTests [\[Details & Test History\]](#)

### ▼ Newly Passing (1)

//javatests/com/google/checkout/external/virtualproxycard/servers:RpcFunctionalTests [\[Details & Test History\]](#)

### ▶ Still Passing (1366)

### ▶ Skipped (223)

- System assumes tests pass or fail reliably given code
  - Tests that don't have this property are "flaky"
- Sources of test flakiness:
  - Infrastructure
    - machine failure
    - environment / setup problems
    - leakage - one test impacting another
    - Overloading resources
  - Tests
    - race conditions
    - external dependencies
    - timeouts
  - Code-under-test
    - memory problems
    - order dependence (e.g. hash tables)

- Causes

- Inability to find changes breaking the build - false positives
- Inability to identify green builds for releases
- Wasted work for build monitors
- Wasted compute resources
- Inappropriately failing presubmits - wasting developer time

- Solutions (Google does all of these):

- Fix them!!!
  - Difficult - requires developer time
- Hide them
  - Retry causing delays
  - Identify infrastructure flakes
  - Use metrics to ignore
- Track them
  - Provide metrics to prioritize fix / hide

- Sources of growth in test execution time
  - More developers = increased submission rate
  - More tests
  - Longer running tests
  - Tests consuming more resources (threading)
- Examine the growth trends
  - Predict compute needs
  - Look for any build system features required

# Build / Test Compute Resources

- Problems
  - Quadratic execution time growth
  - Ultimately cannot run every affected test @ every change
  - Low latency results still top requirement
- Solution: Just in time scheduling (JIT)

## Continuous Integration:

- Run every test affected at every ~~changelist~~.

JIT

as often <sup>^</sup> as possible

## In Production:

- Build and run tests concurrently on Google's distributed build and test backend.

# JIT Scheduling

Schedule tests to run only when system has capacity.

Produce project-wide results at periodic changelists.

## Same User Experience; Lower Cost

### Culprit finding

- Failures / breaks between changes may be more difficult to localize to the offending change.
- **Short-term:** Command-line tool to find culprits
- **Longer Term:** Integrated automatic culprit finding

## Same User Experience; Lower Cost

### Flaky Tests

- Tests which only pass some of the time could cause fewer green statuses for projects.
- **Short Term:** Optionally retry failed tests
- **Longer Term:** Tightly integrated flake mitigation and automatic / manual re-running of suspected flakes

## Q &amp; A
